Radiomic hypothesis

Molecular heterogeneity of cancer lesions is cause of different clinical outcome.

Such heterogeneity can be captured, *in vivo*, on the entire lesion volume, by high-throughput quantitative **radiomics** descriptors from 3D image of cancer lesion.

Different expression level of a signature of radiomic features are able to predict different prognosis or treatment response of patients with similar cancer diagnosis (statistical analysis and predictive models).

doi:10.1371/journal.pone.0124185.g002

Key methodological issues

- **Repeatability**, the closeness of the agreement between the results of successive radiomic measurements under the same conditions of measurement
- **Riproducibility**, the closeness of the agreement between the results of radiomic measurement under similar conditions of measurements
- **Significance**, the ability of radiomic in effectively characterizing cancer lesion heterogeneity

Stability

Biological change or radiomics instability?

It is necessary that the radiomics features are **repeatable** for the same patient as part of the prognosis and therapeutic monitoring but also **reproducible** when performed across multiple centers and patients.

For the SUV and MTV metrics, a cut-off value of $\pm 30\%$ has been accepted for associating the changes to actual metabolic variations (PERCIST).

There is currently no consensus on the tolerated variability of radiomics features for the evaluation of prognosis or response to treatment.

Only radiomic features with high repeatability and reproducibility should be selected as candidate for predictive biomarkers.

³Nuclear Medicine Unit, IRCCS Fondazione S. Maugeri, Pavia, Italy

Coefficient of Variation (COV) can be calculated ($COV < 0.10$ is considered for stability)
but a statistical test is the best choice

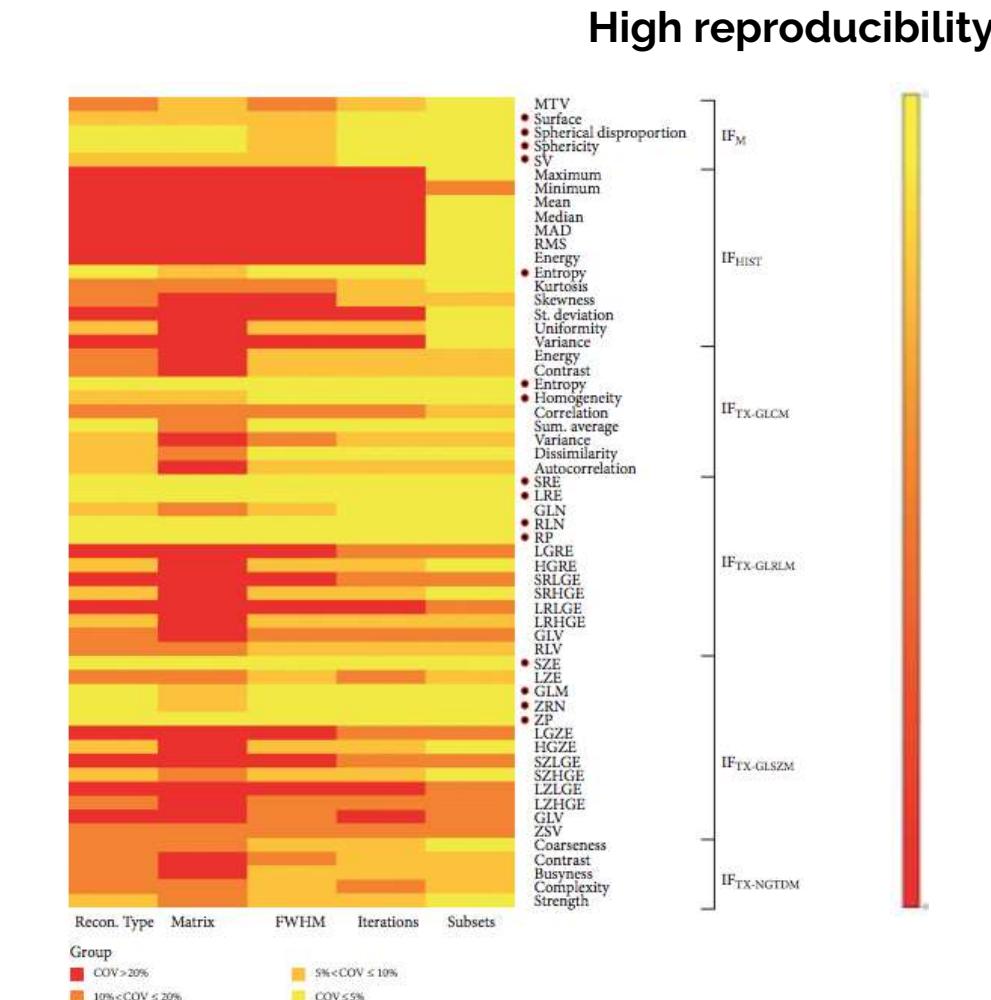

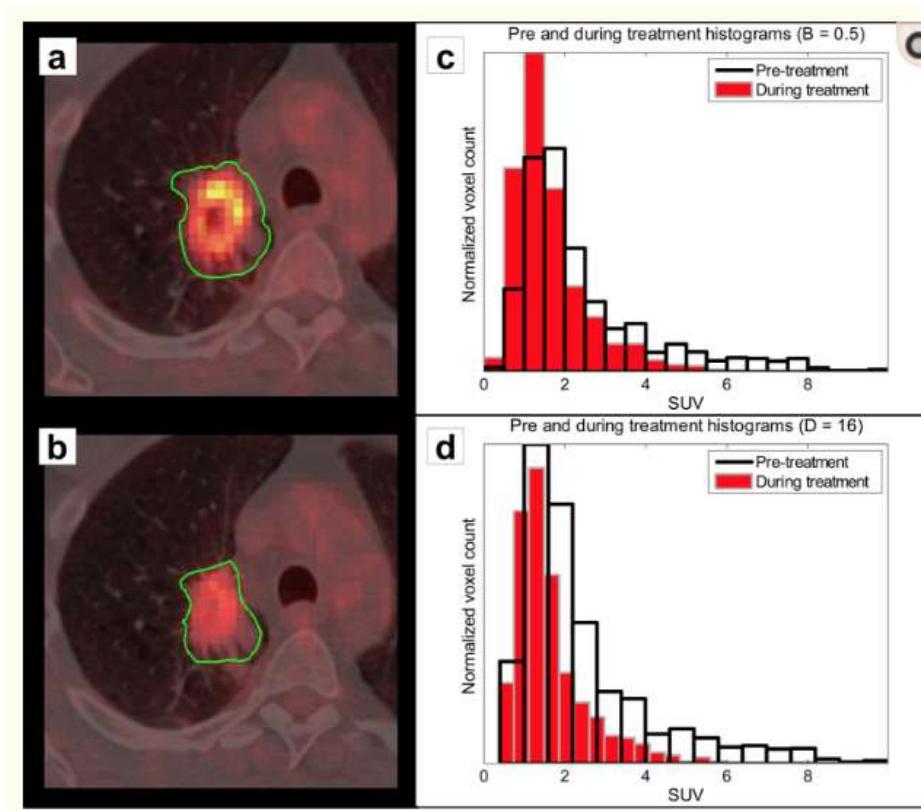

FIGURE 5: Stability of radiomic features on different reconstruction settings. COV results. ● indicates $COV \leq 10\%$

Discretization

Resampling voxels in a limited number of intensity values (bins)
(for textural feature calculation).

Fixed bin size

Fixed bin number

Discretization

Leijenaar et al. 2015 - 35 lung cancer

Texture value is dependent on the method of discretisation

fixed bin size is recommended (constant intensity resolution, more robust, repeatable and less sensitive to segmentation and reconstruction changes)

Lu et al. 2016 - 40 nasopharyngeal carcinoma.

23% of texture features are stable vs **fixed bin size**

Orlhac et al. 2015 - 48 lung cancer & phantom studies /

Desseroit et al. 2017 - 73 lung cancer

fixed bin size is recommended (not requiring MTV of at least 45cc but less intuitive when imaged).

Discretization

Tixier et al. 2011 – 41 oesophageal cancer

Textural features are stable and less correlated with MTV for
fixed bin number (64 bins is recommended since sufficient to cover SUV range of lesions with 0.25 increments).

Segmentation

Segmentation of the tumour volume is a crucial step because
all the radiomics features are calculated starting from the segmented volume.

A variety of methods exists (manual, thresholding, graph-based, region growing, statistical modelling, contour and gradient-based ...)

In radiomics **robustness** (e.g. stability vs noise) is more important than accuracy

Segmentation

Hatt et al. 2013- 50 oesophageal cancer
Entropy, homogeneity showed moderate variability for different segmentation.
No change in radiochemotherapy response.

Leijenaar et al. 2013 - 23 lung cancer
Most textural features **are stable** vs4-operator manual contouring .

Orlhac et al. 2014 - 188 colorectal, lung, breast cancer
Entropy and regional textural **are quite stable** for different segmentation methods.

*Hatt et al. 2018 - **100 lung cancer***
Sphericity, homogeneity and dissimilarity **value changes** depending on the segmentation method
Change in prognosis and prediction of response to treatment.

Image Biomarker Standardization Initiative (IBSI)

They are providing:

- image biomarker nomenclature and definitions
- benchmark data sets and values
- reporting guidelines
- consensus-based guidelines for stable radiomic biomarkers

Zwanenburg A, Leger S, Vallières M, L'ock S. *Image biomarker standardisation initiative*. arXiv preprint arXiv:1612.07003.

Lambin P. *Radiomics Digital Phantom, CancerData* (2016), DOI:10.17195/candat.2016.08.1

Image Biomarker Standardization Initiative (IBSI)

Some recommendations are delivered:
e.g. re-segmentation and discretization

Imaging intensity units ⁽¹⁾	Re-segmentation range	FBN ⁽²⁾	FBS ⁽³⁾
definite	$[a, b]$	✓	✓
	$[a, \infty)$	✓	✓
	none	✓	✗
arbitrary	none	✓	✗

Table 2.1 — Recommendations for the possible combinations of different imaging intensity definitions, re-segmentation ranges and discretisation algorithms. Checkmarks (✓) represent recommended combinations of re-segmentation range and discretisation algorithm, whereas crossmarks (✗) represent non-recommended combinations.

⁽¹⁾ PET and CT are examples of imaging modalities with *definite* intensity units (e.g. SUV and HU, respectively), and raw MRI data of arbitrary intensity units.

⁽²⁾ *Fixed bin number* (FBN) discretisation uses the actual range of intensities in the analysed ROI (re-segmented or not), and not the re-segmentation range itself (when defined).

⁽³⁾ *Fixed bin size* (FBS) discretisation uses the lower bound of the re-segmentation range as the minimum set value. When the re-segmentation range is not or cannot be defined (e.g. arbitrary intensity units), the use of the FBS algorithm is not recommended.

They are working on tolerated variability of radiomics features
but results are not currently disclosed

A possible solution?

A post-reconstruction harmonization method for multicenter radiomic studies in PET

Fanny Orhac, Sarah Bougħadid, Cathy Philippe, Hugo Stalla-Bourdillon, Christophe Niclou, Laurence Champion, Michaël Boussan, Frédérique Frouin, Vincent Frouin and Irène Buval

J Nucl Med.
Published online: January 4, 2018.
DOI: 10.2967/jnumed.117.199935

Harmonization method

To pool SUV and textural features measured from different PET protocols, we tested a harmonization method previously described for genomic studies to correct the so-called batch effect. The ComBat harmonization model developed by Johnson et al (25) assumes that the value of each feature y measured in VOI j and scanner i can be written as:

$$y_{ij} = \alpha + X_{ij}\beta + \gamma_i + \delta_i \epsilon_{ij} \quad \text{Equation 1}$$

where α is the average value for feature y , X is a design matrix for the covariates of interest, β is the vector of regression coefficients corresponding to each covariate, γ_i is the additive effect of scanner i on features supposed to follow a normal distribution, δ_i describes the multiplicative scanner effect supposed to follow an inverse gamma distribution, and ϵ_{ij} is an error term (normally distributed with a zero mean), as explained in Fortin et al (30). ComBat harmonization consists in estimating γ_i and δ_i using Empirical Bayes estimates (noted $\hat{\gamma}_i$ and $\hat{\delta}_i$) as described in (25). The normalized value of feature y for VOI j and scanner i is then obtained as:

$$y_{ij}^{\text{ComBat}} = \frac{y_{ij} - \bar{\alpha} - X_{ij}\bar{\beta} - \hat{\gamma}_i}{\hat{\delta}_i} + \hat{\alpha} + X_{ij}\hat{\beta} \quad \text{Equation 2}$$

where $\hat{\alpha}$ and $\hat{\beta}$ are estimators of parameters α and β respectively. The ComBat harmonization determines a transformation for each feature separately based on the batch (here Department) effect observed on feature values. In the first part of this study, we used ComBat without accounting for any biological covariate (ie $X=0$), and, in the second part, we used the TN status as the covariate of interest.

For each tissue separately (tumor and liver tissues), we applied ComBat harmonization on all features using the R function called "combat" available at <https://github.com/MartinL/ComBatHarmonization/>.

UNPUBLISHED RESULTS (AIRC preliminary)

Conclusions

Radiomic features have been shown to be sensitive to many factors, i.e. preparation & acquisition, reconstruction, segmentation and new ones, more specific of radiomic (e.g discretization).

Factors not only influence the values of radiomics but their extent is highly variable with different results.

These instability generate fluctuations that should not be misinterpreted as being of biological meaning.

Conclusions

Some solutions are coming and collecting from research groups involved in radiomic harmonization initiatives (e.g. IBSI)

It is currently not possible to formally exclude any radiomics feature from future investigations solely based upon their low repeatability and reproducibility.

Until clear recommendations on how to harmonize data are defined, you should select only highly repeatable and reproducible radiomic features from your clinical imaging studies and validate in independent studies to select candidates radiomic biomarkers for prognosis and prediction.

Conclusions

Advanced image processing such as radiomics combined with machine learning can develop models based on imaging signatures for predicting phenotype subtype prognosis and response to therapy

They are opening new role to in vivo medical imaging in predictive personalized medicine

Some radiomic methodological issues (e.g. lesion segmentation, feature harmonization and stability) need robust solutions and validations prior to be traslated in clinical studies

Radiomic predicting models can be improved by liquid epigenomics for integrated phenotype models
